MUSD payments. Verified outcomes.

Merchant orders and paid API access on Mezo.
Direct settlement. Evidence a seller can inspect.

Captured product UI. No illustrative transaction.

Praise / Solo builder

Existing public app: relayguard.vercel.app

Current reviewer build: npm run review

A token transfer leaves an order to reconcile.

The merchant needs to know which order was paid. The API seller needs to know when a response can be released.

Exact intent

Order, payer, asset, amount and recipient.

Buyer authorization

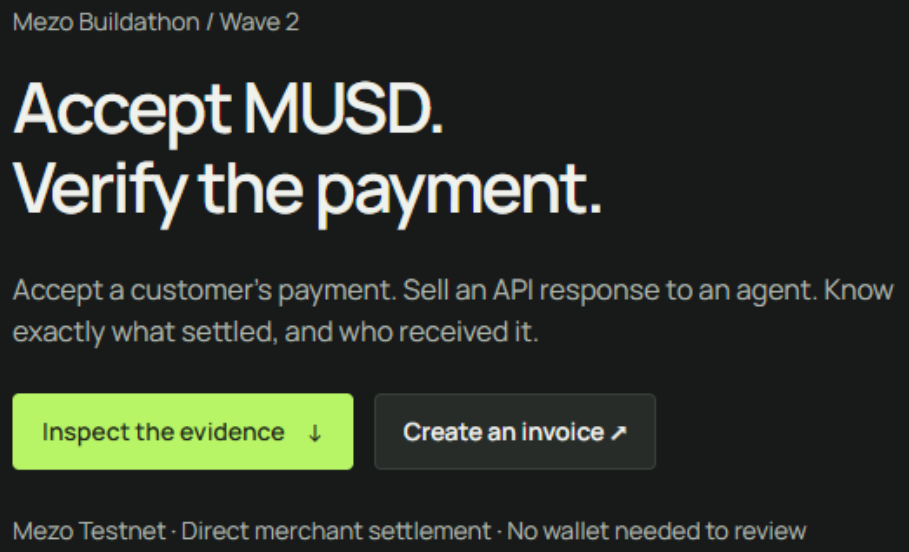

Wallet transfer or signed x402 payment terms.

Verified outcome

Receipt evidence before paid status or resource access.

RelayGuard supplies the payment operations between those steps.

One merchant. Two payment paths.

Customer checkout

A shareable invoice or QR. The buyer signs the exact MUSD transfer directly to the merchant.

Agent API access

HTTP 402 terms. An x402 signature. Facilitator settlement before the API returns its resource.

The merchant retains its storefront, API and wallet.

Mezo is inside the workflow.

MUSD token	Exact merchant settlement Canonical Testnet token. Receipt and Transfer event matching.
Mezo x402	Paid software access Exact MUSD terms and facilitator settlement before delivery.
TroveManager + PriceFeed	Treasury risk evidence Pinned protocol reads retained with the authorization decision.
BorrowerOperations	Optional buyer onboarding Separate Testnet quote, debt review and wallet-signed borrow.

Mezo MUSD guide

Official x402 quickstart

One request. Four risk outcomes.

180%

Within configured limits

125%

Human approval required

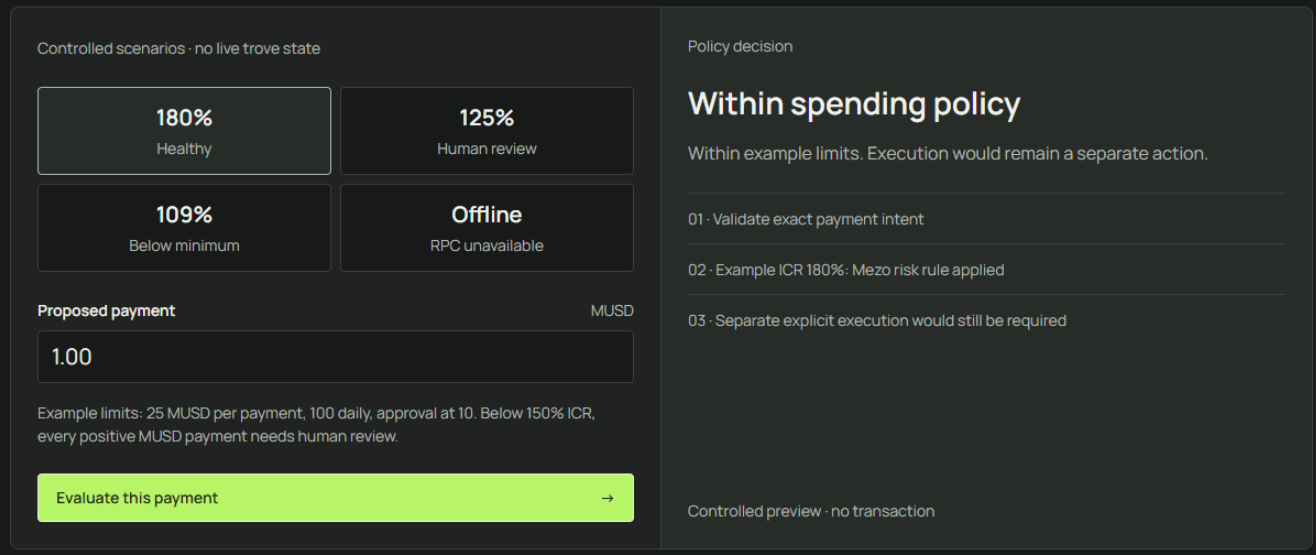

109%

Payment blocked

RPC unavailable: pause MUSD authorization.

What happens when collateral health changes?

Choose a controlled scenario. The server runs the same policy functions used by the operator payment flow. This preview creates no authorization and sends no funds.

110% protocol minimum. 150% app review buffer.

The protocol minimum is a liquidation boundary. RelayGuard adds an earlier review threshold for the configured operator's treasury. Paying a merchant does not itself change trove debt or collateral. Buyer checkout uses separate wallet and balance checks.

Actual policy functions. Controlled examples. No funds move.
Operator treasury policy is separate from buyer checkout.

110% protocol minimum / 150% RelayGuard review buffer

Two historical payments. One receiver.

Payer: 0x2D6d690df41807910826e799A34D7fB418480828

Merchant: 0x840E5bBF20D725f581752f8A4021ADd730550d47

Historical transactions. Fresh RPC verification on capture.

Canonical MUSD + exact amount + expected payer and merchant

Rechecked at Mezo Testnet block 16567090

Stronger boundaries. Recoverable payment attempts.

Treasury access	An explicit operator role protects the shared signer.
Payer identity	An expiring invoice-bound signature proves wallet ownership.
Checkout mutations	Authorization-bound sessions protect submit and release.
Rejection and interruption	Fresh attempts can retry. Stored hashes let submit/verify repair state.
Exact amounts	Excess decimal precision is rejected rather than rounded.

HTTP regression tests use the real app and SQLite stores, with authentication and RPC services mocked. Browser checks cover 390, 768 and 1440 pixel layouts.

A focused first market. A measurable pilot.

API sellers and digital merchants

Already using MUSD. Need verifiable orders and paid access. Keep their storefront and receiving wallet.

$19 / month

Proposed operations tier after free pilots.
No platform fee, revenue or paying customers claimed today.

3 design partners

Next validation gate

Activation

Time to the first verified payment

Reliability

Completed checkouts and support issues

Retention

Repeat weekly use and willingness to pay

Make MUSD usable.
Make payments accountable.

The current build connects Mezo liquidity to useful transactions. The next milestone is repeat merchant use.
