RelayGuard

MUSD payments with protocol-aware controls

Wave 2 · Mezo Testnet

Praise · Solo builder

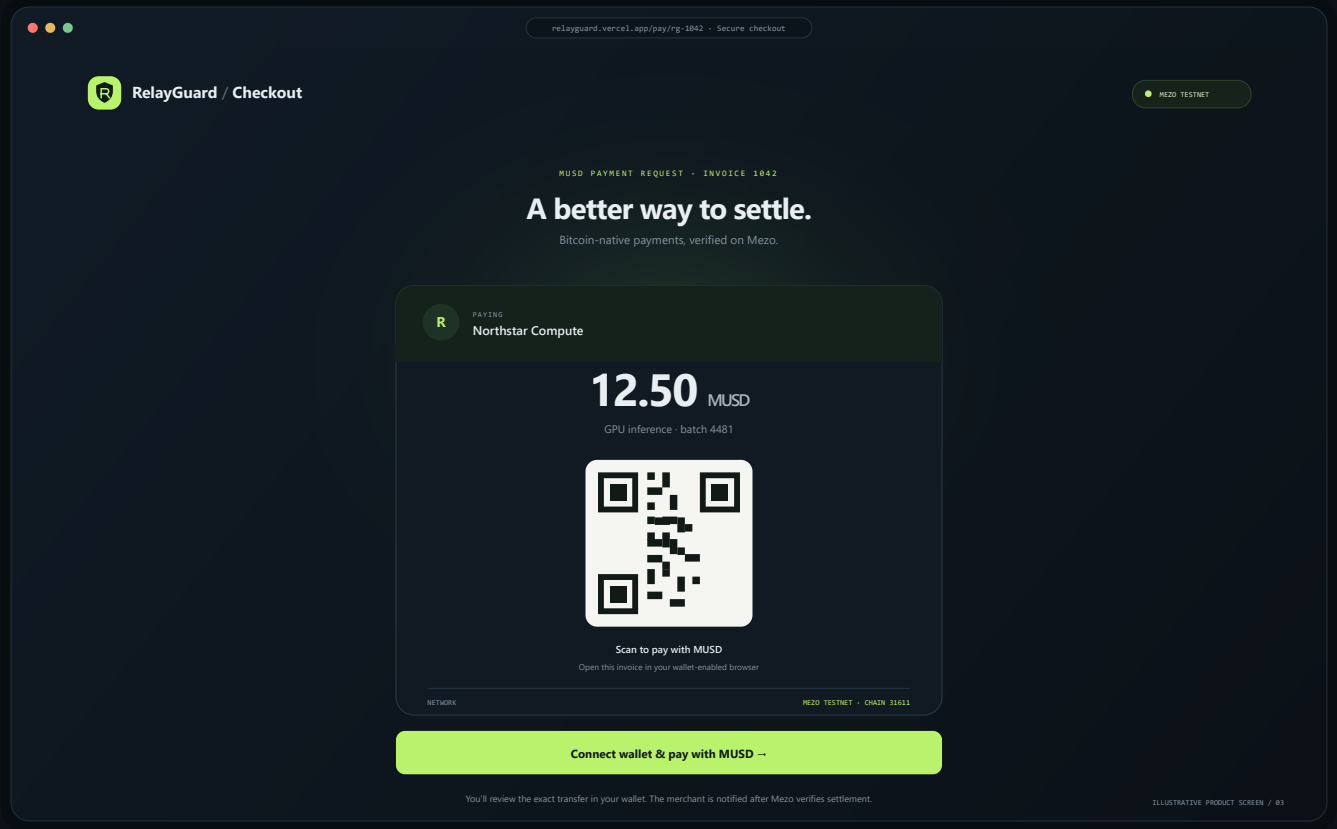

QR checkout for people. x402 access for agents. A Mezo-native spending policy for both.

MUSD needs a safer path into everyday commerce

- Merchants need a simple way to quote, collect, and verify MUSD.
- Agents need exact, machine-readable payment terms before a protected API releases value.
- A generic ERC-20 transfer does not account for the Bitcoin-backed borrowing position that may sit behind an operator's MUSD treasury.

RelayGuard connects the payment to the policy and the relevant Mezo protocol state.

One merchant destination. Two ways to pay.

Illustrative product screen; not a captured live transaction.

- **People:** shareable invoice and QR; buyer signs the exact MUSD transfer.
- **Agents:** x402 exact terms; facilitator settles before API access.
- Both pay the merchant directly; RelayGuard never holds checkout funds.

The Wave 2 difference: policy reads Mezo trove health

RelayGuard reads the configured operator's trove status, Mezo `PriceFeed`, and protocol-computed ICR.

Observed ICR	MUSD agent-payment decision
At least 150%	Configured transaction and daily limits
110% to below 150%	Human approval for every positive payment
Below 110%	Block authorization, approval, and execution
Read unavailable	Fail closed for MUSD; BTC policy unchanged

150% is RelayGuard's review buffer; 110% is Mezo's minimum. These operator controls never open a trove or borrow/add collateral.

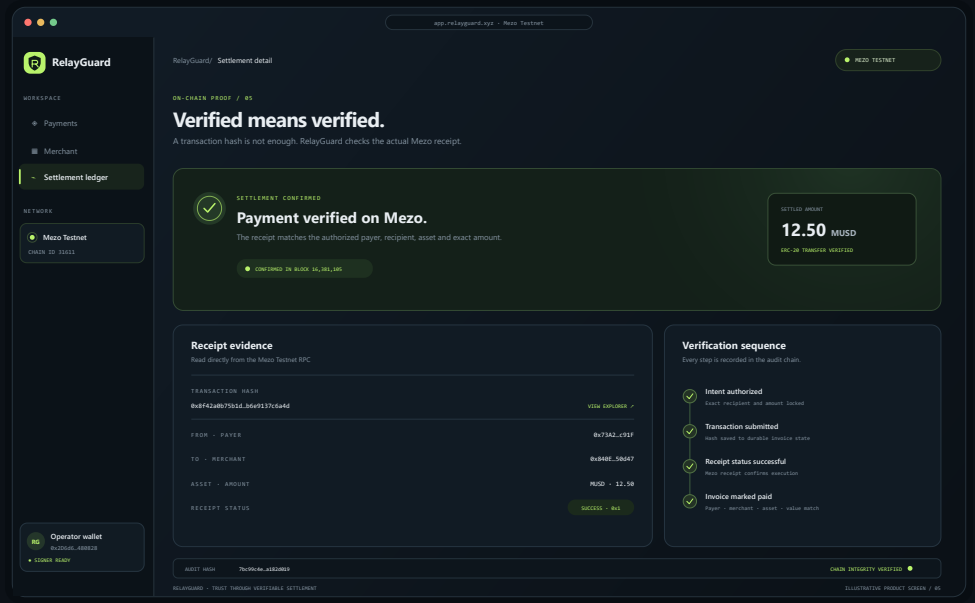

Status: the policy and buyer checkout preflight/optional Testnet trove-opening flow are deployed; 45 automated tests pass, including controlled threshold and RPC-failure cases. A production browser mock reached the underfunded state and rendered a generated QR, but real browser-wallet signing, a valid production invoice QR, and the borrow review with a real wallet remain unverified. No borrow transaction was broadcast for this feature.

Every policy decision is auditable

- The PriceFeed, trove status, ICR, collateral, and debt reads use the same Mezo block.
- Each authorization retains the borrower, price, risk tier, ICR, collateral, debt, block number, and observation time.
- The hash-linked audit chain commits the policy and evidence digests; tampered stored evidence fails verification.
- Approval and execution stop if the risk tier changes. Operators can cancel stale requests; reviewers may still reject them.

The policy uses the operator's trove as a spending signal; it does not open or modify that trove. Separately, an underfunded buyer may opt into a Testnet-only, wallet-confirmed trove-opening flow. Borrowing and invoice payment require separate reviews and transactions; real production wallet testing remains outstanding.

Reliability is part of payment safety

Illustrative product screen; see the linked test evidence for actual settlement records.

- The dashboard loads one protocol snapshot per refresh instead of waiting on sequential, duplicate health reads.
- Merchant invoices and API integrations load concurrently; a new invoice is shown before its activity list refresh completes.
- Checkout labels wallet, balance, authorization, and receipt-verification stages; API calls time out with a retry path.

Evidence from Mezo Testnet

- **1.00 MUSD invoice:** settled to the configured merchant and verified against the exact token transfer.
- **0.001 MUSD x402 resource:** facilitator settlement was verified; the protected resource was returned.
- Both historical payments reached the same merchant receiver.
- **45 automated tests pass locally**, including protocol-risk boundaries, receipt verification, authorization lifecycle, and x402 typed-data signing.

Full transaction references and test limitations: test results. These are testnet results, not mainnet production evidence.

Business model — proposed, not yet enabled

Free pilot for initial merchants, followed by:

- **$19/month** for a merchant workspace with invoices, policy controls, audit history, and agent/API configuration.
- **0.5% fee** on successfully settled MUSD invoices, disclosed before merchant activation.

These are planning assumptions, not current product charges. RelayGuard does not currently collect a platform fee; checkout settlement goes directly to the configured merchant. Validate willingness to pay and unit economics with pilot merchants before enabling billing.

Team

Praise — solo builder

Product ownership and implementation of RelayGuard's merchant checkout, agent-payment flow, Mezo integration, and submission materials.

Ask: feedback and mentorship on merchant adoption, safe treasury policy design, and the path from testnet demo to production-grade payment operations.

RelayGuard

Make MUSD usable. Make agent spending accountable.
